Problem 1 (20 points)

Let $f: \mathbb{R}^n \rightarrow \bar{\mathbb{R}}$ be a convex function attaining its minimum at some point $\bar{x} \in \text{dom} f$.

Show that the sets $\{\text{epi} f, \mathbb{R}^n \times \{f(\bar{x})\}\}$ form an extremal system.

$$\text{Let } \Omega_1 = \text{epi} f, \quad \Omega_2 = \mathbb{R}^n \times \{f(\bar{x})\}$$

Since $\bar{x} \in \text{dom} f$, then $(\bar{x}, f(\bar{x})) \in \Omega_1 \cap \Omega_2$

Now, let $\alpha > 0$ be any positive real number.

We claim that $\Omega_1 \cap (\Omega_2 - (0, \alpha)) = \emptyset$. To prove this

claim, assume otherwise that $(x, \lambda) \in \Omega_1 \cap (\Omega_2 - (0, \alpha))$. Then

$$(x, \lambda) \in \Omega_1 \Rightarrow f(x) \leq \lambda \quad \& \quad (x, \lambda) \in \Omega_2 - (0, \alpha) \Rightarrow x \in \mathbb{R}^n \quad \&$$

$$\lambda = f(\bar{x}) - \alpha. \quad \text{So } f(x) \leq f(\bar{x}) - \alpha \Rightarrow f(x) - f(\bar{x}) \leq -\alpha < 0$$

i.e. $f(x) < f(\bar{x})$. This is a contradiction; since

$$f(\bar{x}) \leq f(x) \quad \text{for all } x \in \mathbb{R}^n.$$

Let $\mathcal{R} = \mathbb{R}[x]$ and $\mathcal{R}' = \mathbb{R}[x, y]$

Since $\mathcal{R} \in \mathcal{R}'$, then $(\bar{x}, f(x)) \in \mathcal{R}' \cap \mathcal{R}$

Now, let $\alpha > 0$ be any positive real number.

We claim that $\mathcal{R}' \cap \mathcal{R} = \mathcal{R}$. To prove this

claim, assume otherwise that $(x, y) \in \mathcal{R}' \cap \mathcal{R}$. Then

$$(x, y) \in \mathcal{R}' \Leftrightarrow f(x) < y \text{ or } (x, y) \in \mathcal{R} \Rightarrow x \in \mathcal{R}$$

$$y = f(x) - x. \text{ So } f(x) < x \Rightarrow f(x) - x < 0 \Rightarrow x < 0$$

is $f(x) < f(x)$. This is a contradiction, since

$$f(x) \leq f(x) \text{ for all } x \in \mathbb{R}.$$

Problem 2 (20 points)

Let $\bar{x} \in \text{dom } f$, where $f: \mathbb{R}^n \rightarrow \bar{\mathbb{R}}$ is an extended real-valued convex function.

- (a) If f is continuous at \bar{x} , show that $\bar{x} \in \text{int}(\text{dom } f)$.
 (b) If $\bar{x} \in \text{int}(\text{dom } f)$, show that $\partial^\infty f(\bar{x}) = \{0\}$.

(a) Assume that f is continuous at \bar{x} . Then for every $\epsilon > 0$, there is a $\delta > 0$ such that if $x \in \mathbb{B}(\bar{x}; \delta)$, then $|f(x) - f(\bar{x})| < \epsilon \iff f(x) - f(\bar{x}) < \epsilon$
 $\implies f(x) < f(\bar{x}) + \epsilon < \infty$ because $\bar{x} \in \text{dom } f$
 $\therefore x \in \text{dom } f \quad \forall x \in \mathbb{B}(\bar{x}; \delta)$; which shows that $\bar{x} \in \text{int}(\text{dom } f)$.

(b) Assume that $\bar{x} \in \text{int}(\text{dom } f)$, then $N(\bar{x}; \text{dom } f) = \{0\}$
 but $\partial^\infty f(\bar{x}) = N(\bar{x}; \text{dom } f) = \{0\}$.

Problem 3 (20 points)

Let $f : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$ be an extended real-valued convex function and let $\bar{x} \in \text{dom } f$ be a local minimizer of f .

- (a) Show that f attains its global minimum at this point.
 (b) Is the global minimizer \bar{x} unique? why?

Ⓐ Assume that \bar{x} is a local minimizer of f . That is there is a $\delta > 0$ such that $f(x) \geq f(\bar{x}), \forall x \in \mathcal{B}(\bar{x}; \delta)$.
 Now let $y \in \mathbb{R}^n$ & consider the sequence $\{y_k\}$ defined as

$$y_k = \left(1 - \frac{1}{k}\right)\bar{x} + \frac{1}{k}y, \quad k \in \mathbb{N}.$$
 Then $y_k \in \mathcal{B}(\bar{x}; \delta)$ for large enough k . By the convexity of f , we have

$$f(\bar{x}) \leq f(y_k) \leq \left(1 - \frac{1}{k}\right)f(\bar{x}) + \frac{1}{k}f(y) \Rightarrow \frac{1}{k}f(\bar{x}) \leq \frac{1}{k}f(y)$$
 or $f(\bar{x}) \leq f(y)$. So \bar{x} is a global minimizer.

Ⓑ No, For example $\mathcal{S}(\bar{x}; [-1, 1])$, $x \in \mathbb{R}$
 the set $[-1, 1]$ is a set of minimizers

(a) Assume that \bar{x} is a local minimizer of f . That is there is a $\delta > 0$ such that $f(x) \geq f(\bar{x}) \forall x \in B(\bar{x}; \delta)$.
 Now let $\{x_k\} \subset \mathbb{R}^n$ & consider the sequence $\{f(x_k)\}$ defined as

$$x_k = (1 - \frac{1}{k})\bar{x} + \frac{1}{k}y, \quad k \in \mathbb{N}. \text{ Then } x_k \in B(\bar{x}; \delta) \text{ for}$$

 large enough k . By the convexity of f , we have

$$f(x_k) \leq f(\bar{x}) \leq (1 - \frac{1}{k})f(\bar{x}) + \frac{1}{k}f(y) \Rightarrow \frac{1}{k}f(y) \leq \frac{1}{k}f(\bar{x})$$

 or $f(y) \leq f(\bar{x})$. So \bar{x} is a global minimizer.

(b) No, for example $f(x) = |x|$, $x \in \mathbb{R}$.
 the set $[-1, 1]$ is a set of minimizers.

Problem 4 (20 points)

Consider the set $\Omega \subset \mathbb{R}^2$ defined as

$$\Omega = \{x = (x_1, x_2) \in \mathbb{R}^2 \mid 3x_1^2 + x_2^4 \leq 1\}$$

(a) Give a brief justification why Ω is convex.

(b) Find $N(\bar{x}, \Omega)$ where $\bar{x} = \left(\frac{\sqrt{5}}{4}, \frac{1}{2}\right)$.

Let $f: \mathbb{R}^n \rightarrow \mathbb{R}$ be as $f(x_1, x_2) = 3x_1^2 + x_2^4$. Then the set Ω is the level set Ω_1 for f .

(a) $\nabla f(x_1, x_2) = \begin{pmatrix} 6x_1 \\ 4x_2^3 \end{pmatrix} \Rightarrow \nabla^2 f(x_1, x_2) = \begin{pmatrix} 6 & 0 \\ 0 & 12x_2^2 \end{pmatrix}$ which is positive semidefinite of all $(x_1, x_2) \in \mathbb{R}^n$. Therefore f is convex and all its level sets are convex.

(b) (1) $f(\bar{x}) = 3\left(\frac{5}{16}\right) + \frac{1}{16} = 1$
 (2) $\partial f(\bar{x}) = \left\{ \nabla f(\bar{x}) \right\} = \left\{ \begin{pmatrix} \frac{3\sqrt{5}}{2} \\ \frac{1}{2} \end{pmatrix} \right\} \therefore 0 \notin \partial f(\bar{x})$
 (3) f is continuous at \bar{x} being a polynomial.

So $N(\bar{x}; \Omega) = \mathbb{R}_+ \partial f(\bar{x}) = \left\{ \lambda \begin{pmatrix} \frac{3\sqrt{5}}{2} \\ \frac{1}{2} \end{pmatrix} : \lambda \geq 0 \right\}$.

Problem 5 (20 points)

Let $f: \mathbb{R}^2 \rightarrow \mathbb{R}$ be the convex function defined as

$$f(x_1, x_2) = \max\{|x_1|, |x_2|\}, \quad \text{for all } x = (x_1, x_2) \in \mathbb{R}^2.$$

Find $\partial f(x)$ for all $x \in \mathbb{R}^2$. Then find

(a) $\partial f(0,0)$.

(b) $\partial f(1,1)$.

(c) $\partial f(0,1)$.

let $f_1(x_1, x_2) = |x_1|$, $f_2(x_1, x_2) = |x_2|$. Then

$$\partial f_1(x_1, x_2) = \begin{cases} e_1, & x_1 > 0 \\ -e_1, & x_1 < 0 \\ \lambda e_1 - (1-\lambda)e_1, & x_1 = 0, \lambda \in [0, 1] \end{cases} \quad \text{where } e_1 = (1, 0) \\ e_2 = (0, 1)$$

$$\partial f_2(x_1, x_2) = \begin{cases} e_2, & x_2 > 0 \\ -e_2, & x_2 < 0 \\ \lambda e_2 - (1-\lambda)e_2, & x_2 = 0 \end{cases}$$

So for $(x_1, x_2) \neq (0,0)$

$$\partial f(x_1, x_2) = \text{co} \left\{ (\text{sign } x_i) e_i \mid |x_i| = f(x_1, x_2), i \in \{1, 2\} \right\}$$

$\neq \partial f(0,0) = \text{co} \{ \pm e_1, \pm e_2 \} \leftarrow \underline{(a)}$

(b) $\partial f(1,1) = \text{co} \{ e_1, e_2 \}$

(c) $\partial f(0,1) = \text{co} \{ e_2 \}$

Let $|x| = (x_1, x_2) \in \mathbb{R}^2$. Then $f(x) = (x_1, x_2)$.

$$g_f(x) = \begin{cases} e^{x_1} & x_1 > 0 \\ e^{-x_1} & x_1 < 0 \end{cases}$$

where $g_f = (1, 0)$
 $g_f = (0, 1)$

$$g_f(x) = \begin{cases} e^{x_1} & x_1 > 0 \\ e^{-x_1} & x_1 < 0 \\ 0 & x_1 = 0 \end{cases}$$

20. For $(x_1, x_2) \neq (0, 0)$
- (a) $g_f(x) = \cos \left\{ \frac{1}{\sqrt{x_1^2 + x_2^2}} \right\}$
 - (b) $g_f(x) = \cos \left\{ \frac{1}{\sqrt{x_1^2 + x_2^2}} \right\}$
 - (c) $g_f(x) = \cos \left\{ \frac{1}{\sqrt{x_1^2 + x_2^2}} \right\}$
